

Posterior draws of regional baselines:

$$\alpha_j^s, \quad j \in \{1, \dots, 6\} \text{ (regions)}, \quad s \in \{1, \dots, n\}, \quad n = 20,000$$

Step 1 – Rank within each posterior sample:

- Within each posterior draw, the six regional baselines α_j^s are ranked 1–6.
- Ties are assigned the mean of the ranks they share.

Step 2 – Average ranks across draws:

$$\hat{r}_j = \frac{1}{n} \sum_{s=1}^n r_j^s \quad \leftarrow \text{posterior mean rank}$$

Step 3 – Rank the mean ranks:

$$r_j^* = \sum_{i=1}^6 \mathbf{1}(\hat{r}_j > \hat{r}_i) \quad \leftarrow \text{final regional ranking}$$
